In-class activities

February 4, 2010
Afternoon class results

How many unpaired valence electrons are there in a nitrogen atom?

A. One.
B. Two.
C. Three. [Correct answer]
D. Five.

How many bonds is nitrogen able to make?

A. One.
B. Two.
C. Three. [Correct answer]
D. Five.

The neon atom tends NOT to gain any additional electrons because
A. its nuclear charge is not great enough.
B. that would result in a positive ion.
C. of the repulsions they would have with electrons in the same shell.
D. there is no more room available in its outermost occupied shell.

An atom loses an electron to another atom. Is this a physical or a chemical change for the atom that lost the electron?

A. Physical change involving the formation of negative ions. [Correct answer]
B. Chemical change involving the formation of negative ions.
C. Physical change involving the formation of positive ions.
D. Chemical change involving the formation of positive ions.

Magnesium ions carry a 2+ charge, and chloride ions carry a 1− charge. What is the chemical formula for the ionic compound magnesium chloride?

A. MgCl
B. MgCl₂
C. MgCl₂ [Correct answer]
D. Mg₂Cl₂

1.
2.
3.
4.
What is the chemical formula for calcium chloride?

1. Any of these could be it
2. CaCl
3. Ca₂Cl
4. CaCl₂
5. Ca₂Cl₂

The formula can be determined by paying attention to the valence electrons: calcium has 2, that’s why it’s in group 2; and chlorine has 7, like all elements in group 17. Chlorine has a place for one more electron in it’s valence shell, and it collects this one from the calcium. But since calcium has two available, two chlorines take advantage of this.

The resulting molecule has a net charge of zero: 2 chlorine bonded to 1 calcium.

A hydrogen atom does not form more than one covalent bond, because it
A. has only one shell of electrons.
B. has only one electron to share.
C. loses its valence electron so readily.

Atoms of metallic elements can form ionic bonds, but they are not very good at forming covalent bonds. Why?
A. These atoms are too large to be able to come in close contact with other atoms.
B. They have a great tendency to lose electrons.
C. They are on the wrong side of the periodic table.
D. Their valence shells are already filled with electrons.

When nitrogen and fluorine combine to form a molecule, the most likely chemical formula is

A. N₃F
B. N₂F
C. NF₄
D. NF
E. NF₃

Classify the following bond as ionic, covalent, or metallic (Na, atomic number 11; Cl, atomic number 17)

Na with Cl  Na with Na  Cl with Cl

A. metallic, covalent, covalent
B. ionic, metallic, covalent
C. ionic, ionic, covalent
D. covalent, metallic, ionic

How many electrons are used to draw the electron-dot structure for hydrogen peroxide, a covalent compound with the formula H₂O₂?

A. 14  B. 8  C. 7  D. 4
