</tbody>
</table>

% error

\[
\frac{(8.56g/ml)-(8.77g/ml)}{(8.56g/ml)} \times 100 = -2.45% \\
\frac{(2.7g/ml)-(2.75g/ml)}{(2.75g/ml)} \times 100 = -1.85% \\
\]

Possible reasons for the error include rounding errors, not reading the volume accurately, not weighing the cylinders accurately. NEVER say human error. Tell me what the error is!

Part B:

Activity 2: this activity looks at surface tension and water and how it changes due to the addition of a detergent. The detergent causes a lower surface tension due to the disruption of the hydrogen bonds between the water molecules. You should have noticed that when you dropped the detergent in the center of the thread that it “pushed” the thread out from the center and then the thread sank. The thread sinks because of lower surface tension. When the detergent is dropped beside the thread, it causes the thread to be “pushed” to the side of the dish.

Activity 3: Surface tension is also responsible for the number of water drops you can put on a penny. The idea behind surface tension is that water molecules attract each other so they “pull” together. This “stickiness” allows many drops to be placed on a penny. I got 31 drops. The number varies between 20 and 35. Why is there so much variance? What are possible sources of error?

Part C

The purpose of these experiments was not just to figure out which sample was water but to do a series of experiments in a consistent manner. Some of the important techniques include washing your equipment with distilled water between experiments and making sure volumes of solids and liquids were the same for each experiment. Additionally, observation is also very important. For example, noticing if something totally dissolves or how the oil floats on the liquid. The page below were the results of my experimentation and some of the things I noted:

PG10:

Based on my experiments I decided #2 was the water sample. This was due to the pH, The way the oil floated on the surface (similar to the water sample), and the evaporation experiment. I decided 1 wasn’t based on the pH value, 3 wasn’t since it left a residue after evaporation and it didn’t dissolve the salt or sugar, and 4 wasn’t due to the way the oil spread out on the top of the solution rather than beading up.

Be sure you spend some time thinking about the most and least effective tests and the “whys” associated with them. Make sure the why you come up with is specific and not a generic answer.
